

# Claim Videos Classification Project | TikTok

## Hypothesis Testing

### Executive Summary

#### Overview

As part of claim video classification project, our data team was tasked to conduct hypothesis testing. This report shows the procedure we follow and key insights delivered from the statistical analysis.

#### Problem

The main purpose was to define if there was a relation between `author verification status` (i.e. verified or not verified) and average `video views`.

#### Solution

A hypothesis test was performed to define whether the relation between these two parameters is statistically significant or due to chance alone.

#### Details

First of all, we performed some descriptive statistics that helped us understand the main data characteristics quickly and deleted the null values that could affect our test.

#### Test Steps:

- At first we state the null and alternative hypothesis as follows:  
**Null hypothesis:** There is no effect of author verification status on number of video views.  
**Alternative hypothesis:** There is an effect of author verification status on number of video views.
- After setting a significance level of 5% and calculation the p-value we concluded that we can reject the null hypothesis.

#### Test Results:

There is a strong effect of author verification status on number of video views which is statistically significant.

#### Next Steps

- Our next step is to develop a logistic regression model that is further clarifies the relation exist between author verified status and the video views and how this is related to claim status.
